

# Using JS

Only experience can teach

- All the options available
- How to break down a problem

But...

- Some best practices can save you a lot of time

# State

An application has "state"

- The current values for all things that can change

A chat application

- Are you logged in?
- As who?
- Are there messages?
- What are they?
- Are you typing a message?

# **How to store state**

Store your state in variables/object

Use those to update the screen as needed

Do not read the HTML (DOM) to recapture the state

# How NOT to store state

Example: You show a list of users on the screen.

To get the list of users, should you read the DOM?

**No.** Why?

- The screen is the visual output
- if you alter the display, you change how to get the list that way
- As your display gets more complicated, so does all your state interaction

# **Model-View-Controller (MVC)**

MVC is a common best-practice pattern for many situations:

- Something manages your data (model)
- Something the flow of the application (controller)
- Something translates the data to output (view)

You can see this is in the chat-mpa assignment

We will change a lot, but that breakdown will remain

# Debugging JS

When something isn't working

- There are a few ways to tackle the problem
- There are a few things NOT to do

# Narrow the scope

FIRST: make sure you know what's wrong

- Validate you know up to which point things work
- Check for error messages
- Check values of fields and properties

Don't spend time fixing the wrong "problem"

*Which line isn't working as you expect?*

# Checking for errors

In Node, check the console output for error messages

In Browser, check the console

- console erased on page load unless "preserve log"
  - redirects are page loads

Network subtab holds info on network calls

- check for errors
- separate "preserve log" option here

# Check values

## Inspect Element

- Are CSS classes and HTML properties correct?
- Is your CSS selector matching? overridden?

## Network

- Check to see that form fields were passed
- Verify the correct method (GET/POST/etc) is used
- Check status code
- Check values in response

# Console.log

"old" saying, basically:

```
When I was a new coder, I relied on console.log
```

```
When I was an senior coder, I relied on debuggers
```

```
When I was a master coder, I relied on console.log
```

`console.log` is fine **IF**

- You clean it up before submitting (!)
- You know the triggering state

# Browser Debugger

"Sources" subtab

- "Watch" a variable visible to the current scope
- "Breakpoints" to stop on
  - Can make conditional stops
  - Requires page reload if code already done
- "Scope" to see other variables
- "pretty print" minified code (lower left )

# Client side storage

Sometimes you want to store information outside of the page *on the browser*

- Cookies
- localStorage
- IndexedDB

## BE CAREFUL

- Limited security
- Users will change browsers/machines
- Can get changed/deleted by user/browser
- Not all clients are browsers

# Cookies

"Cookies" are just an HTTP header

- Special is how browsers treat them
- Browser sends cookies along with each request

Cookies are text-based key/values pairs

- limited to a URL and descendant paths
- might have expiration date
- might (should) require HTTPS
- might not be accessible to JS
- shared between tabs

# When to use cookies

Most Common:

- Store a random key that is IS also server-side
  - a "session" identifier
- request with key lets server read extra data
- Depends on that random number staying secret
- Cookie/session should NOT hold **application** state
  - because user might be using multiple tabs
  - each page/tab has its own application state
  - session data is useful regardless of state

# **When not to use cookies**

DO NOT use cookies to store:

- Sensitive data (CC numbers, passwords)
- Personal data (addresses, etc)
- Application state
- Big data
- Data hard to represent in short bits of text

# Local Storage

localStorage and sessionStorage

- key/value
- client-side only (not sent to server)
- JS only (no JS, no using localStorage)
- Store bigger values than cookies
- localStorage is shared between tabs
  - sessionStorage is NOT
- localStorage does not expire
  - sessionStorage lasts until browser quits
- Still domain-limited
  - Not path limited

# When to use localStorage

- Store JS-applicable preferences
- When data too awkward for cookies
- When user switching devices isn't a problem
- To keep tabs in sync with choices

Rarely want sessionStorage

- Lack of tab-sharing causes confusion

# **When NOT to use localStorage**

- Cookie security restrictions still apply
  - Sensitive data (CC numbers, passwords)
  - Personal data (addresses, etc)
- If the data is needed without JS

# IndexedDB

Browser-side object-based DB

- NOT relational, NOT table-based

Asynchronous

- Like a click handler: response will happen later

JS-only

Stores larger data, non-expiring

- Browser can limit and/or delete without warning

# **When to use IndexedDB**

Fairly few cases

Transactions

Larger data, but unreliable storage

Non-trivial to use

# When NOT to use IndexedDB

- Cookie security restrictions still apply
  - Sensitive data (CC numbers, passwords)
  - Personal data (addresses, etc)
- If the data is needed without JS
- If you don't want the complexity

# What is a Polyfill?

Polyfills add newer functionality to older JS

Example:

- `forEach()` is a method on Arrays
- takes a callback, calls that callback with each element in turn

You can write this in JS versions prior to it being standard

# How do Polyfills work?

- Check to see if the feature exists
- If not, add the new function to the prototype

Why all methods in MDN refer to `Foo.prototype.`

- The **only** time you modify native prototypes
- Someone else has done this for you

# JS Tools

JS ecosystem has many tools beyond the engine

- linters
- minifiers
- bundlers
- transpilers

# Linters

Linters (not JS-specific): programs to check syntax

- For purely stylistic preferences
- For patterns that are technically correct
  - but tend to lead to errors

Formatting is long debated

Linters can help find unintended errors

`eslint` is the most common JS linter

- Many IDEs have linting built-in

# Prettier

- Newer tool (JS only?)
- Auto-formats code to a common style
- Popular among those that don't want to argue

# Minifiers

- Removes unneeded whitespace
- Replaces variable names with short ones
  - where possible

Reduces file size of JS/CSS/HTML

Makes them harder to read/debug

Is NOT security

Smaller size CAN matter

# Bundlers

Frontend struggles to handle multiple JS files well

"bundlers" convert multiple files into one

- Some use NodeJS `require()` syntax
- Others use the newer standard `import` command

Common bundlers:

- Webpack
- Rollup
- Browserify

# Browsersify - an example bundler

```
// Commands
mkdir b-ify
cd b-ify
npm init -y
npm install browserify
```

```
// foo.js
const bar = require('./bar');
console.log(`The other file says ${ bar() } successfully`);
```

```
// bar.js
module.exports = function() {
  return `I like cats`;
};
```

```
// Commands
browserify foo.js -o bundle.js
```

```
// index.html
<script src="bundle.js"></script>
```

# Transpilers

Transpilers are "**trans**forming comp**ilers**"

- input (something)
- output JS

Examples:

- Input typescript, output JS
- Input clojurescript, output JS
- Input modern JS, output older JS
- Input **future** JS, output modern JS

Example: See Babel at [\*\*https://babeljs.io/\*\*](https://babeljs.io/)

# Hot reloading

During Front end development, it is common to have a setup that will reload your changes easily

- great during development
- not great for when the product is shipped

# In This Course

- We will start without tools
  - Your IDE might have linting
  - We will add some tools
  - Section 3 will use a few
- Tools make things easy
  - But understand the concepts without them
  - You aren't lost if they aren't working

BUT: You may think WebDev is annoying
